Job-Market Paper

“Precautionary saving, wage risk, and cyclical reallocation”

Abstract: Workers face wage risks associated with job-to-job transitions, which are comparable in magnitude to unemployment risk but largely beyond the reach of traditional social security safety nets. I examine the consequences of cyclical variations in wage risk by introducing a job ladder into the state-of-the-art Heterogeneous Agent New Keynesian model. The dynamic job ladder propagates productivity shocks through two channels: fluctuations in worker reallocation rate between jobs and cyclical variations in relative wages. Adverse productivity shocks lead to an endogenous increase in wage risk, triggering a strong precautionary-saving response that depresses consumption and output. I find that endogenous fluctuations in wage risk amplify recessions by 40% compared to a scenario with no dynamic job ladder, with the predominant share of the amplification arising from changes in reallocation rates.
